

Figure 1

Figure 2

**Conclusions:** The study results reveal a significant relationship between normalized GAGs and BMI in this population of osteoarthritic patients. Higher patient BMI ( $>30 \text{ kg/m}^2$ ) may be similar to dynamic compression injuries that cause increased GAG synthesis in response to cartilage damage. The lack of significance at day 5 and 13 may be the result of OA tissue variability and significance may be achieved with increased sample numbers. In conclusion, elevated normalized GAGs in obese patients' chondrocytes suggests increased cartilage damage.

### THE EXPRESSION OF NOTCH SIGNALING COMPONENTS IN OSTEOARTHRITIS

P.G. Alexander, S.M. Koehler, R.S. Tuan  
National Institutes of Health, Bethesda, MD

**Purpose:** This study aims to investigate the role of Notch signaling in the pathogenesis of osteoarthritis (OA). The Notch signaling pathway is a highly conserved signaling system that plays a critical role in cell proliferation, differentiation, and apoptosis in the context of stem cell differentiation. Thus, aberrant regulation of Notch signaling may adversely affect cartilage repair by altering chondrogenesis of mesenchymal stem cells (MSCs) in diseased tissue.

**Methods:** Human OA cartilage was obtained from surgical waste material following total knee arthroplasty or from normal joint tissue (from the National Disease Research Interchange). Human chondrocytes (hCh) and bone marrow MSCs were isolated using established methods. Quantitative RT-PCR was utilized to analyze transcript levels of Notch signaling components in OA and normal tissue and monolayer cultures of hChs and MSCs. Histological staining was performed with H&E, alcian blue, alizarin red, Fast Green, and Safarin O. MSCs and hChs were cultured in high-density pellets in serum-free chondrogenic medium. To

mimic OA conditions, pellets cultures were treated with  $0.1 \text{ ng/mL}$  IL-1 $\beta$  for 21 days. Harvested pellets were analyzed histologically and for gene expression as described above.

**Results:** Expression of Notch1, Notch2, Jagged1, and Delta1 is down regulated in OA compared to normal cartilage 200-, 12-, 34-, and 30-fold, respectively (Fig. 1). Notch1 expression is highly expressed in normal cartilage, absent in monolayer hChs, and similarly expressed in monolayer MSCs and OA cartilage. During MSC chondrogenesis in vitro, Notch1 is down regulated in the IL-1 $\beta$  treated cultures compared to expression in the untreated cultures at days 7 and 21 (5- and 65-fold, respectively) (Fig. 2). Notch2, Notch3, Jagged1, and Delta1 expression decrease from day 7 to 21 with or without IL-1 $\beta$  treatment. In addition, Sox9 is also down regulated in the treated compared to untreated cultures at days 7 and 21 (18- and 5-fold, respectively) (Fig. 3). In comparison, during chondrogenesis of hChs in vitro, Notch1 increases in untreated cultures from day 7 to 21 (5-fold), but is unexpressed in day 21 IL-1 $\beta$  treated hChs (Fig. 2). All Notch components are expressed at lower levels in untreated hChs compared to treated. Overall, chondrogenesis gene expression was down regulated in IL-1 $\beta$  treated cultures (Fig. 3).

**Conclusions:** The down regulation of notch components in OA cartilage suggests that its poor regenerative capacity may be related in part to reduced chondrogenic differentiation of chondroprogenitor cells. Support is provided from the results of the MSC in vitro chondrogenesis study - under OA conditions, i.e., IL-1 $\beta$  treatment, Notch expression is down regulated and chondrogenesis is impaired. For hChs, in vitro chondrogenesis is accompanied by increased Notch expression, whereas chondrogenesis gene expression is decreased under OA conditions. Therefore, hChs appear to dedifferentiate and are prevented to undergo chondrogenesis in the presence of IL-1 $\beta$ . Similar cellular reactions may also take place under OA conditions in vivo, resulting in a decrease of hChs and MSCs able to undergo chondrogenesis; instead, the cells may differentiate into alterna-

Figure 3 - mRNA Expression Levels of Chondrogenic Genes during Chondrogenesis In Vitro

tive lineages, contributing to the inappropriate remodeling in OA. Taken together, our results suggest the Notch signaling pathway plays an important role in the pathogenesis of OA via potentially impairing the repair capacity of the diseased tissue.

<sup>1</sup>Center of Diagnosis and Treatment for joint disease, Drum Tower Hospital Affiliated to Medical School of Nanjing University, Nanjing, China; <sup>2</sup>National Resource Center for Mutant Mice, Nanjing University, Nanjing, China

**Purpose:** The primary aim of this study was to investigate, using an experimental rat model of osteoarthritis(OA), the effect of a selective p38 mitogen activated protein kinase inhibitor, SB203580, on the development of structural changes. Additional aims were to assess the effects of the inhibitor on levels of matrix metalloproteinase 3 (MMP-3) and MMP-13(collagenase 3) in OA cartilage and to explore the relation between the MMP-3,13 expression and the severity of OA.

**Methods:** OA was induced in 40 SD rats by anterior cruciate ligament transection (ACLT). After surgical, rats with OA were randomly divided into A\_D groups: Rats of group A received 0.1 ml intra-articular injection of SB203580 at high concentration of 100µm/L. Each treatment started immediately after surgery, once a week; those in group B were treated under the same condition using SB203580 with low concentration of 10µm/L and those in group C received 0.1ml of intra-articular 0.9% Sodium Chloride injection, animals of group D were not injected as controls after ACLT. The animals were killed 8 weeks after surgery. Macroscopic and histologic studies were performed on the cartilage. The levels of MMP-3,13 in OA cartilage chondrocytes were evaluated by immunohistochemistry and western-blotting.

**Results:** All ACLT knees demonstrated osteoarthritic changes. Cartilage degradation in the control group was significantly more severe than that in the experimental group both on the macroscopic grading scale and on Mankin's grading scale ( $P < 0.05$ ). Immunohistochemical study showed that in the experimental group MMP-3,13 was predominantly expressed in the superficial and upper intermediate layers of cartilage, and the amount of MMP-3,13 in the experimental group was also lower than that in control group ( $P < 0.05$ ). In western-blotting the amount of MMP-3,13 was reduced by the treatment of the inhibitor. The protein levels of MMP-3 and MMP-13 in cartilage of inhibitor injection groups were significantly lower than those of Sodium Chloride group and untreated group. There was no significant difference in MMP-3 and MMP-13 expression between the different con-

centration inhibitor injection groups. No significant difference in MMP-3 and MMP-13 expression in cartilage was found between Sodium Chloride group and control group.

**Conclusions:** This study demonstrates that, in vivo, SB203580, a selective inhibitor of p38MAPK, can partially decrease the development of some of the structural changes in the early phases of experimental OA and significantly reduces the severity of cartilage degradation. This effect was associated with a reduction in the level of MMP-3,13 in OA cartilage, which probably explains the action of the drug and thus may be a potential drug for the treatment of OA.

### INVOLVEMENT OF TYROSINE PHOSPHORYLATION IN THE ACTIVATION PROCESS OF THE VOLUME SENSITIVE CL<sup>-</sup> CHANNEL IN RABBIT ARTICULAR CHONDROCYTES

N. Okumura<sup>1</sup>, F. Toyoda<sup>2</sup>, E. Isoya<sup>1</sup>, M. Kubo<sup>1</sup>, K. Ando<sup>1</sup>, T. Mimura<sup>1</sup>, K. Uenaka<sup>1</sup>, S. Imai<sup>1</sup>, H. Matsuura<sup>2</sup>, Y. Matsusue<sup>1</sup>

<sup>1</sup>Department of Orthopaedic Surgery, Shiga University of Medical Science, Otsu, Shiga, Japan; <sup>2</sup>Department of Physiology, Shiga University of Medical Science, Otsu, Shiga, Japan

**Purpose:** Mechanical loading of articular cartilage influences the metabolism of extracellular proteoglycan and collagen matrix and thereby alters the osmotic environment surrounding chondrocytes. Previous studies have identified the presence of the stretch-activated cation channels, mechanosensitive K<sup>+</sup> channels and volume-sensitive Cl<sup>-</sup> channels ( $I_{Cl,vol}$ ) in chondrocytes, suggesting that these mechanosensitive ion channels contribute to cell volume regulation. Pathological swelling of chondrocytes observed in osteoarthritic (OA) cartilage may be ascribed at least partly to the impairment of channel function involved in the volume-regulatory process. The present study was designed to elucidate the mechanisms underlying activation of  $I_{Cl,vol}$  in rabbit articular chondrocytes using whole-cell patch-clamp method.

**Methods:** Rabbit cartilages were collected from bilateral knee, hip and glenohumeral joints of male animals weighing 2.0 to 3.0 kg. The cartilage was dissected into slices and cultured in DMEM for 1-3 days, and chondrocytes were isolated by enzymatic digestion on the day of experiments. Whole-cell membrane current was recorded during exposure to isosmotic (300 mOsm), hyposmotic (210 mOsm) and hyperosmotic (350 mOsm) external solutions under conditions where Na<sup>+</sup>, K<sup>+</sup> and Ca<sup>2+</sup> currents were minimized. In some experiments, the stretch-activated cation current was also blocked by external application of 30 µM Gd<sup>3+</sup>.

**Results:** Exposure of chondrocytes to the hyposmotic solution resulted in a cell swelling (27.0±2.7% increase in diameter,  $n = 28$ ), which was accompanied by the activation of  $I_{Cl,vol}$ . External application of tyrosine kinase inhibitor genistein (30 µM) partially (42.0±14.3%,  $n = 7$ ) and reversibly blocked  $I_{Cl,vol}$  but its inactive analogue daidzein (30 µM) had no effect. On the other hand, intracellular application of tyrosine phosphatase inhibitor orthovanadate (250 and 500 µM) via a recording pipette gradually activated an outwardly rectifying current with a reversal potential (-20.3±0.58 mV,  $n = 13$ ) close to the predicted Cl<sup>-</sup> equilibrium potential ( $E_{Cl^-} = -18.3$  mV) even under isosmotic condition. This orthovanadate-evoked current was almost completely abolished by the stilbene-derivative Cl<sup>-</sup> channel blocker DIDS (dihydro-4,4'-diisothiocyanostilbene-2,2'-disulphonic acid, 500 µM) and was also largely reduced by cell shrinkage caused by exposure to hyperosmotic solution. These observations indicate that orthovanadate activates a Cl<sup>-</sup> conductance which is sensitive to cell volume change. Pretreatment of chondrocytes with genistein significantly prevented the activation of Cl<sup>-</sup> current by orthovanadate, suggesting that the basal activity of tyrosine kinase is required for the orthovanadate-evoked activation of Cl<sup>-</sup> current.
